

Remote Development Project Report

Student Name: Your Name

Student ID: Your Student ID

1. System Configuration

This assignment was completed in an Ubuntu virtual machine environment. I used Linux command-line tools to check the CPU information, memory size, operating system version, GCC compiler version, and Python version.

The commands used were:

```
lscpu
free -h
uname -a
gcc --version
python3 --version
```

The collected system information is shown in Appendix A.

2. Implementation Details

This project implements matrix multiplication using Python.

For two matrices A and B, the element in row i and column j of the result matrix C is calculated by multiplying the corresponding elements from row i of matrix A and column j of matrix B, then summing the products.

The formula is:

$$C[i][j] = A[i][0] * B[0][j] + A[i][1] * B[1][j] + \dots + A[i][k] * B[k][j]$$

The program uses three nested loops:

1. The first loop iterates through the rows of matrix A.
2. The second loop iterates through the columns of matrix B.
3. The third loop computes the dot product for each position in the result matrix.

3. Python Implementation

The source code file is named `matmul.py`.

The program can be executed with the following command:

```
python3 matmul.py
```

The program contains three main parts:

1. `matmul(A, B)`: implements matrix multiplication.
2. `verify()`: verifies correctness using a small example.

3. `performance_test(size)`: records the execution time for different matrix sizes.

4. Correctness Verification

To verify the correctness of the algorithm, I used a small example that can be checked manually.

```
A = [[1, 2],  
      [3, 4]]
```

```
B = [[5, 6],  
      [7, 8]]
```

According to the rule of matrix multiplication:

```
C[0][0] = 1*5 + 2*7 = 19  
C[0][1] = 1*6 + 2*8 = 22  
C[1][0] = 3*5 + 4*7 = 43  
C[1][1] = 3*6 + 4*8 = 50
```

Therefore, the expected result is:

```
[[19, 22],  
 [43, 50]]
```

The program output matches the expected result, so the implementation is correct.

5. Running Result

The output of running the Python program is shown in Appendix B.

6. Conclusion

Through this assignment, I practiced basic Linux command-line operations, including creating directories, checking system information, writing files, and running programs from the terminal.

I also implemented matrix multiplication in Python and verified the correctness of the algorithm using a manually calculated example. This assignment helped me understand how command-line tools, Markdown documentation, and Python programming can be combined in a simple remote development workflow.

7. References

1. Course slides: Lecture 3, UNIX/Linux environment and Shell.
2. Course slides: Lecture 4, Command Line Environment and Remote Development.
3. Python official documentation.

4. GNU GCC documentation.

Appendix A. System Information
